RESUME ADDENDUM • ROLE CONTEXT & SELECTED WORK

This addendum accompanies my resume. A resume compresses work into single lines, which tends to preserve what was built and lose why it was built that way. The material below expands on the scope of my current role, the reasoning behind several architecture decisions, and the constraints those decisions were made under. It is written to be read alongside the resume rather than in place of it.

1. ROLE CONTEXT — TITLE VS. OPERATING SCOPE

My title at Source One Spares is Solutions Engineer. The role I actually perform is broader than that title suggests, and I would rather explain the gap directly than let it be discovered mid-process.

I joined in February 2024 into a role scoped around data analysis, business reporting, and solution support. Over the following two years the company grew from \$26M to \$53M to \$81M in revenue. The technology function did not grow with it; scope consolidated into the role I already held. Today I own the following domains as a single position:

Domain	What I own
Salesforce Platform Architecture	Data model, security model, permission set and profile architecture, automation strategy, Apex and Lightning Web Component development, integration design
Cloud & Infrastructure	AWS backup architecture, data protection and retention strategy, recovery planning, cloud integrations
Business Systems Engineering	Process automation, third-party integrations, accounting and procurement workflow, operational improvements
AI & Technology Enablement	AI adoption strategy, phased Claude implementation, user enablement, responsible-use guardrails — a standing function, not a completed project
Technology Governance	Technical standards, platform evolution decisions, security and compliance support, vendor and technology evaluation

In most organizations this scope is distributed across roughly five positions — Salesforce architect, cloud engineer, business systems administrator, automation engineer, and an AI enablement lead — each reporting into technology leadership. The advantage of consolidating it has been speed and coherence: architecture decisions do not have to be negotiated across teams, and the platform stayed consistent while the business tripled. The cost is capacity and key-person concentration, which is a structural fact rather than a complaint.

The practical relevance to a hiring conversation: my title understates the work, and I am looking for a role where the title, scope, and authority match from the start.

2. SELECTED CASE — A PRODUCTION FAILURE WITH NO ERROR MESSAGE

I include this one because it is the clearest evidence of how I work, and because the difficulty of it is not visible from a resume bullet.

- The presenting problem.** Automate purchase-order approval routing in Salesforce. On its face, a routine configuration task.
- The actual problem.** Approval submissions were being cancelled roughly two seconds after creation. There was no error message, no failed-record notification, and nothing in the standard system logs. From the user’s perspective the submission simply did not exist. The cause was a conflict between the internal approval process and protected background code inside the AvSight managed package — code that cannot be inspected or modified.
- Diagnosis.** Because standard logging showed nothing, I queried Salesforce’s internal audit tables directly and analyzed the execution timing patterns across submissions. The timing signature is what identified the conflict; nothing in the ordinary troubleshooting surface would have surfaced it.

Three approaches evaluated and rejected

- Direct modification of the conflicting logic — blocked by managed-package restrictions. The code is sealed by the vendor.

- An alternative platform-native approach — blocked by Salesforce platform limitations in that execution context.
- A time-delay workaround — rejected on business grounds before it was built. It would have appeared to work in testing. It would also have failed intermittently once real users began editing PO line items after submission, producing an approval process that mostly works and occasionally recalls a PO silently. In a procurement workflow that is an audit exposure, not an inconvenience. This was the more important of the three rejections, because it was the one that would have shipped.

The solution

A Platform Event queue that decouples approval submission into a separate, clean transaction, removing the resource conflict entirely. This is the same event-driven pattern used to resolve contention in payment processing and order management systems. It was implemented declaratively — no custom code, no changes to the vendor package, no dependence on undocumented platform behavior — and it scales with transaction volume without modification.

Time distribution. Roughly 90% of the effort went to understanding the problem and 10% to building the fix. That ratio is normal for root-cause work and is the inverse of what a fast workaround produces: a quick resolution with an invisible liability underneath it.

3. SALESFORCE GOVCLOUD MIGRATION

Source One Spares supports government and DoD business, which requires operating in a compliance-aligned environment. I led the migration of the full production AvSight/Salesforce environment out of the native environment and into GovCloud.

- Object and data migration across the full org, including custom configuration and historical records.
- Permission architecture rebuilt rather than copied — a migration is one of the few opportunities to correct accumulated permission drift instead of carrying it forward.
- Security model alignment against the compliance requirements of the target environment.
- Automation migration, followed by post-cutover validation and troubleshooting across affected business processes.

This ran alongside ongoing operational support rather than as a dedicated project with backfill.

4. TOWER — CROSS-SYSTEM SEARCH PLATFORM

The recurring operational problem was not missing data; it was that answering a single business question required touching several disconnected systems, and the time cost of that lookup was paid many times a day across the company.

I designed and built Tower, a search layer that branches across those systems and connects them into a single retrieval path, then delivered successive iterations as usage patterns clarified what people were actually looking for.

Internally, the platform has been estimated at approximately \$2M in annual business value. I want to be precise about that figure: it is an internal estimate of time and efficiency recovered, not an audited financial result, and I present it as such.

5. DATA PROTECTION — AWS BACKUP & RECOVERY ARCHITECTURE

Salesforce's native protections do not constitute a backup strategy, and the gap is easy to miss until it matters. I designed and implemented a full backup architecture on AWS, along with the supporting infrastructure required for it to run reliably and unattended.

- Coverage extends beyond standard records to binary files and bulk datasets — the categories most often left out of a nominal backup and most painful to lose.
- Retention model, data protection strategy, and recovery planning designed as one thing, since a backup with no tested recovery path is a filing system.
- Scoped external access: limited-permission AWS access shared with third parties where required, with dedicated integration users rather than shared credentials.

6. AI ADOPTION & GOVERNANCE

I lead AI adoption for the organization as a standing function rather than a rollout project, on the view that adoption keeps producing new governance questions as capability expands.

- Phased implementation of Claude across the organization, with user enablement rather than tool distribution — adoption failures are usually enablement failures.
- Responsible-use guardrails, including deliberate restriction of MCP (Model Context Protocol) access during controlled rollout. Connecting a model directly to production systems is a meaningfully different risk posture than assisted work, and I did not want that decision made implicitly.

- Ongoing evaluation of AI and adjacent technology for organizational fit.

7. GOVERNMENT / DOD SUPPORT & COMPLIANCE

I support the government and DoD business line with the workflows, automation, and process design that operating in that space requires.

On CMMC certification I want to be accurate about my role: I contributed as a supporting team member, assisting with implementation and gap remediation. I was not the lead driver of the certification effort, and I would not want that inferred from a resume line. Related to this, I have applied self-directed cybersecurity knowledge to help close organizational gaps where the need appeared and no one else was positioned to address it.

8. TECHNOLOGY ENVIRONMENT

Salesforce: Apex, Lightning Web Components, SFDX, SOQL, Flow, Platform Events, approval processes, permission set and profile architecture, managed-package constraint navigation (AvSight), GovCloud.

Cloud & identity: AWS (backup architecture, storage, retention, recovery), Microsoft Entra application registrations, connected apps, OAuth, integration user provisioning.

Data & reporting: SQL/T-SQL, Python, Power BI, Tableau, SSRS, ETL and data migration, dashboard design tailored by user profile.

Delivery: Agile/Jira, GitHub, REST/JSON API integration, Postman, technical documentation and standards.

9. CAREER ARC — WHY THIS PATH READS THE WAY IT DOES

My background moves from quantitative and data work into platform architecture, which is less common than the reverse and shows up in how I approach problems. The consistent thread is not a technology or an industry — it is analysis and system design applied to whatever the domain happened to be.

- At BNY Mellon I built and maintained deal models for CDO/CLO structures, then led a team of 9–12 analysts doing the same. That work established the habit of treating data discrepancies as signals with causes rather than records to correct.
- In application support at NOV I worked root-cause analysis on production systems at scale, which is directly upstream of how I approached the approval-process failure described above.
- My M.S. in Technology Commercialization (UT Austin, McCombs) is a STEM-designated program in technology transfer and commercialization strategy — a formal credential in the business-to-technology translation function, rather than a general technical or business degree.

The through-line is that I have not specialized into either the technical or the business side. I do the architecture and the implementation, and I can explain the tradeoff to a developer and the risk to an executive in the same conversation.

10. WHAT I AM LOOKING FOR

A principal or staff-level architecture role on an individual-contributor track — scope and decision authority over architecture, standards, and governance, rather than people management. I am open to management later; I am not seeking it as the mechanism for advancement now.

I am industry agnostic, and I mean that structurally rather than as a willingness to adapt. My depth is not a vertical. It is system design, analysis, and architectural reasoning — decomposing an ambiguous problem, finding the constraint that actually governs it, and designing something that holds under that constraint. Aviation aftermarket, financial services, and energy are where I have applied that; they are not what I know. The underlying problems — data and security modeling, integration under vendor constraints, resilience, governance under compliance requirements — are the same problems wearing different domain vocabulary.

Paired with an M.S. in Technology Commercialization, that combination covers what a technical executive function actually consists of: deciding what should be built, judging whether a proposed solution is structurally sound before it is committed to, and translating between the engineering case and the business case without losing either one. I have been performing that function without the title. I am looking for a role where the two align.

References, additional detail on any item above, and walkthroughs of the technical decisions are available on request.
